# **1. INTRODUCTION**

# 1.1 SCOPE

This document will describe the 1394 Device Discovery and status retrieval (DDsr(1394.x)) Protocol Specification which should apply to all devices that connect to the IEEE1394 High Performance Serial Bus. The specification will provide a flexible method for any device to comply to.

# 1.2 PURPOSE

This purpose of this protocol specification is to define a universal, method for simple discovery of functional units and low-level service discovery within a IEEE1394 device. What will be described is;

- A methods for identifying a DDsr(1394.x) compliant node.
- A method for identifying a functional unit (or multiple functional units) within a DDsr(1394.x) compliant node.
- A method for retrieving information on each of the functional units.
- definition of the DDsr(1394.x) protocol to support the above functions.

# 1.3 BACKGROUND

Even though the current IEEE1394-1995 specifies the configuration ROM format following rules of the IEEE 1212 -1994 standards, thus allowing IEEE1394 node discovery, it does not define a common method for discovering the function units within a particular node.

Currently, there are communication protocols focused on IEEE1394 communication such as the Function Command Protocol (FCP) used with the AV command set, and the Serial Bus Protocol-2 (SBP-2) which acts as a lower-layer to command sets. Some of these communication protocol stacks each provide a method for discovering the function units of the node, <u>but under the condition that the discovery will be accomplished within that particular protocol</u>. There may be other protocols that do not support function discovery at all.

In any case, definition of a universal method for discovery of functional units and low-level service discovery is necessary and will be useful for any 1394 device.

# 2. DEFINITIONS

# 2.1 TERMINOLOGY

### Datalink

In this document, a "datalink" will be defined as the (or part of the) lowest layer above the transaction layer defined in the IEEE1394-1995 specification. It will be the lowest layer of the printer protocol stack in the communication protocol stack.

#### Transport

In this document, a "transport" will be defined as the set of communication protocol stacks as a whole. The set will consist of protocol layers ranging from the data-link layer to the application layer.

### **Node Discovery**

In this document, a "node discovery" will be defined as discovering a IEEE1394 node and information which will include DDsr(1394.x) protocol compliance. Other node information discovery will include manufacturer and ,model number, global unique ID of the nodes which are defined in the IEEE1394-1995 specification.

## **Unit (function) Discovery**

In this document, a "unit (function ) discovery" will be defined as discovering a functional unit (or multiple units) within a IEEE1394 node. A unit or unit class will be categorized by the functionality such as Examples of units would be image output units, image source units.

#### Low-level service Discovery

In this document, "Low-level service discovery" is defined as discovering the availability of the datalinks (=lowest layer above 1394 transaction layer), and the entry points of the datalinks.

#### **Device Discovery**

In this document, "device discovery" will consist of discovery of the following;

- Node Discovery
- Unit Discovery
- Low-level Service discovery

# **3. OVERVIEW/FUNCTIONAL CHARACTERSTICS**

### 3.1 Overview

This proposal for the DDsr(1394.x) Protocol will not define nor specify a transport, or datalink, but will define an inquiry method for discovering the function units within a node, and the transports, or datalinks which the units will support. Examples of function units would be printers, scanners, video cam-corders etc. Examples of datalinks will include XXX over SBP-2 and the AV/C protocol as well as vendor-specific protocols. The DDsr(1394.x) Protocol will provide information on unique Ids of each function units, as well as status of each units.

#### "DDsr(1394.x) Protocol" Capable Nodes

**Nodes that are capable of the DDsr(1394.X) protocol** connecting to a DDsr(1394.x) compliant target node will execute the DDsr(1394.X) protocol. As a result of this protocol execution, the initiator device can discover the function units within the target node, and datalink capability of each unit, and it's entry point. If the initiator discovers the preferred function and supported datalink, it will enable it and make logical connection. From this point on until the image source disconnects, the printer can be controlled using the transport enabled.

#### Non-"DDsr(1394.x) Protocol" Capable Nodes

Nodes that are not capable of the DDsr(1394.X) protocol will follow the procedures defined in the communication protocols it supports. This may differ from node to node, so nodes may not be able to establish device discovery or low-level service discovery.

## 3.2 Operational Model

The following section will describe procedures of the DDsr(1394.x) IEEE1394 device.

- The operational model
- Interfaces

A IEEE1394 node will support the DDsr(1394.X) Protocol and one or more

communication protocols. The DDsr(1394.X) Protocol is defined in this document, and examples of communication protocols may be FCP+AV/C and protocols using SBP-2 as the base layer. It may also be a device specific protocol. The DDsr(1394.X) Protocol will be used to discover a (DDsr(1394.X) Protocol compliant) device node, the first discover the function unit (s) of the node, and secondly find out the communication protocols each unit supports.

A basic discovery scheme using DDsr(1394.x) will take the following sequence.

- 1. A initiator device will look into (read) the defined address in the configuration ROM of the target node to discover a DDsr(1394.x) compliant device node.
- 2. The initiator device will read out information for the address of the Function\_unit directory block, which will store information on the function units available in the node.
- 3. The initiator will read out the Function\_unit directory block and retrieve supported function units of the target node, and pointers for leafs blocks of each unit.
- 4. If further information is needed on a given function unit, the initiator will read out the leaf block of the function unit which pointer was given in the directory block. The function unit leaf block stores a list of datalink(s) supported by that particular unit, and the pointer to the entry of that datalink. It will also store information on unit-uniuqe Ids(example: Plug and play string)
- 5. Initiator device will enable the datalink that matches the capabilities of both the initiator and target.

## 3.3 Interface

Printers will at least support asynchronous bi-directional interfaces that will be used for the DDsr(1394.X) Protocol.

In this revision, this section will describe 2 different methods, the register map mode and the command / response mode. For the register map mode, a IEEE1212 format is described.

This is for study purposes, and <u>1 method will be defined as the minimum requirement in the final</u> specicfication.

# 4. DDsr(1394.X) PROTOCOL DEFINITION

This section will describe the details of the DDsr(1394.X) protocol. <u>The identification of the DDsr(1394.X) Protocol compliant deivce will be defined in</u> <u>the Node spec. ID of the Root directory in the configuration ROM.</u> The DDsr(1394.X) protocol will define and provide 4 main functions:

- 1. Function 1: Function Unit Discovery
- 2. Function 2: Low level service discovery of each unit
- 3. Function 3: Unique ID information retrieval of each unit
- 4. Function 4: Status retrieval of each unit

In other words, the DDsr(1394.X) protocol will allow retrieving information on the functional units within a node, and information on each of the functional units such as the communication protocols each one supports, and some unit Ids unique to each unit.

In the case of nodes having multiple function units, information on the multi-function node **as a whole** can be retrieved as an option.

Fig 4.1 shows the basic architecture and hierarchy of discovery in the DDsr(1394.X) protocol

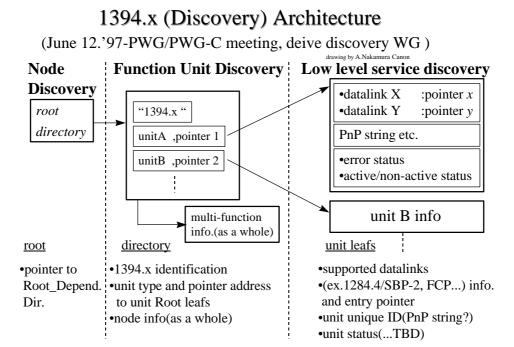

fig 4.1

# 4.1 Configuration ROM

The Node\_spec.\_ID and the Node\_dependent \_info Directory offset of the Root Directory, of the configuration ROM will be defined by the DDsr(1394.X) Protocol. The Module\_spec.\_ID and the Module\_dependent \_info Directory offset of the Root Directory is also defined for optional usage.

Address Locations are with respect to the Root Directory which has a base address of:

FFFF F000 0000h

## Node\_Spec\_ID entry ...ROOT DIRECTORY

This field will identify that this device will support the DDsr(1394.X) protocol

Offset	0-7	8-15	16-23	24-31
0420h	0Ah	node_specid	(TBDDDsr(139	94.X))IEEE?

## Node\_dependent \_info Directory offset ...ROOT DIRECTORY

This field will identify the offset address of the DDsr(1394.X) Function\_unit directory entry.

Offset	0-7	8-15	16-23	24-31
0428h	D0h	node_dep	endent_info direc	tory offset

FYI: The Specification for Power Management has it's own (special) root directory offset entry using the key\_value of F0h(concationation of 3h and 30h) which 30h-37h is reserved for definition by the bus standard identified in BUS\_INFO\_BLOCK. (Which is IEEE1394 in this case.)......31h for DDsr(1394.x)?

# 4.2 DDsr(1394.X) Register Map Method

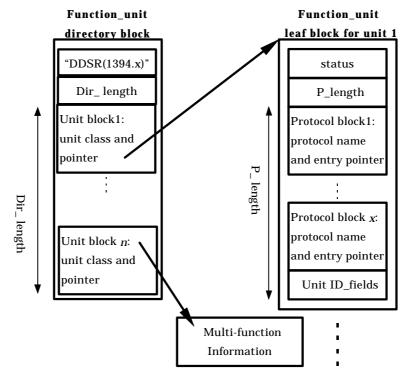

The DDsr(1394.X) Register map of a node consists of 2 main parts; 1 Function\_unit directory block and 1 or more Function\_unit blocks. Readouts of the DDsr(1394.X) register map will be done using the read transactions defined in the IEEE1394-1995 specification.

The Function\_unit directory block will store information on the function\_units within a node. In detail, it will give information on ;

- the function\_class of each unit in the node
- pointer to the Function\_unit leaf block for each unit

The Function\_unit leaf block will store information of each of the function\_units within a node. In detail, it will give information on ;

- the protocols supported by the unit
- entry pointer of each of the protocols
- status information of the units

Nodes with multiple function units will have multiple unit blocks, and units supporting multiple datalinks will have multiple protocol blocks.

Information of the multi-function units as a whole (multi-function information) can also be stored in the Functional unit leaf block.

# 4.2.1 Function\_ unit directory block (unit discovery)

Address offset locations noted in this section are with respect to a base address noted in the Node\_Dependent\_Info Directory offset in the configuration ROM.

Offset	R/W	0-7	8-15	16-23	24-31
0000h	R	directory length		CRC16	
0004h	R	00xxxxxb	5	spec_identifie	r
0008h	R	00xxxxxb	configu	aration_state	counter
000Ch	R	00xxxxxxb		dir_length	
0010h	R	01xxxxxb		pointer	<b>≜</b>
0014h	R	00xxxxxxb	f	uctunit_clas	s
0018h					
	R	01xxxxxb		pointer	
	R	00xxxxxb	f	uctunit_clas	s
	<b>-</b> Key	_type Key_values			,

#### 4.2.1.1 Spec\_identifier

The Spec\_identifier field is used to identify compliance with the DDsr(1394.X) protocol.

Field	Bit	Description
spec_identifier	[831]	"DDsr(1394.X)"

## 4.2.1.2 Configuration state counter......RAM implementation only

TBD

The Configuration change counter field shows a value of a state-change ring counter. A state-change counter shall increment the value by 1 when there is a configuration change in the supported function units or the information of any of the functional units.

Canon Inc.

1		
	D	
	1	B

		TBD
Field	Bit	Description
Configuration	[831]	counter value of state-change counter
state counter		

#### 4.2.1.3 Dir\_length

The Dir\_length field is used to inform the remaining length of the Function\_unit directory block. The value of this field will represent the remaining length of the block in number of quadlets. (refer to above register map)

Field	Bit	Description
Dir_length	[831]	remaining length of block in quadlets

4.2.1.4 Unit block (Pointer / Fuct.\_unit\_class)

The Pointer field and Fuct.\_unit\_class field are the pair of fields that make up a unit block for each function\_unit in the Function\_unit directory block. The value of the Fuct.\_unit\_class field will represent the functional class of the unit, and the value of the pointer field will represent the pointer address of the Function\_unit leaf block of the unit it represents.

Field	Bit	Description
Pointer	[831]	pointer address of the Function_unit leaf block

Field	Bit	Description		
Fuctunit_class	[831]	functional class of the unit		
		0 : others		
		1 : printing function		
		2:		
		i i i i i i i i i i i i i i i i i i i		

From IEEE std 1212 document:

# Node\_Dependent Info

Used to provide additional information about the node.

The leaf or directory Node\_Dependent \_Info provodes vendor-dependent information. The format and meaning of this information is dependent on the 48-bit value produced by prepending the 24-bit Node\_Vendor\_ID value to the 24-bit Node\_HW\_Version number

## **Key definitions**

# 4.2.2 Function\_ unit leaf block (low-level service discovery)

Address offset locations noted in this section are with respect to the pointer address of each functional\_unit noted in the Pointer field of the Function\_unit Directory block. (section6.2.1)

Offset	R/W	0-7	8-15	16-23	24-31	
0000h	R	leaf_i	length	Cl	RC	
0004h	R		functional	unit_status		
0008h	R		p_le	ngth		
000Ch	R				<b>≜</b>	
0010h	R		protoco	l_name	p le	Protocol
0014h	R				length	Block
0018h	R		entry_n	ode_no.		
001Ch	R	keytype	e	entry address		J
	R		entry_n	ode_no.		
	R		entry a	uddress		
	R		ID_le	ength		
	R		unit_iı	nfo_ID	D_lengt	
	R		IDV_	length	h	
	R		vendor_u	nique_ID	DV_length	
					gth	

# 4.2.2.1 Functional unit\_Status.....RAM implementation only

The Status field is used to inform the basic (primitive) functional status of the unit.

TBD

			TBD
Field	Bit	Description	
Status/Active	[30]	0 : unit is in non-active state	
		1 : unit is in active state	
Status/Error	[31]	0 : no error	
		1 : error	
	[1629]	reserved	

### 4.2.2.2 P\_length

The P\_length field is used to inform the total length of the protocol blocks in this Function\_unit leaf block. The value of this field will represent the field length in number of quadlets. (refer to above register map)

If a Protocol block is not used, the value of the P\_length will be 0.

Field	Bit	Description
P_length	[031]	length of protocol blocks in quadlets

4.2.2.3 Protocol\_block(Protocol\_name,entry\_node\_no,entry\_address)

The Protocol block is comprised of 4 fields; the Protocol\_name field, the entry\_node\_no. field, and the entry\_address field with a key\_type to specify the characteristics of the entry\_address field.

The Protocol\_name field is a 3 quadlet field used to inform the supported datalinks of the function\_unit.

Field	Bit	Description
Protocol_name	[031]	The name of the datalink supported by
		the unit .

The entry\_node\_no. and entry\_address field will inform the node\_ID and the entry set address of the datalink noted above.

Field	Bit	Description	
entry_node_no.	[031]	nodeID	
key_type	[01]	<ol> <li>intial-register space offset for a immediate value</li> <li>indirect-space offset for a leaf</li> <li>indirect-space offset for a directory</li> <li>others: not used.</li> </ol>	
entry_address	[231]	address for datalink entry.	

### 4.2.2.4 ID\_length

The ID\_length field is used to inform the total length of the Unit\_info\_ID field for this Function\_unit leaf block. The value of this field will represent the field length in number of quadlets. (refer to above register map)

Field	Bit	Description
ID_length	[031]	length of Unit_info_ID field in quadlets

## 4.2.2.5 Unit\_info ID

The multi-quadlet Unit\_info ID field is used to inform an unique ID of the function unit. The contents of the Unit\_info ID field will follow the format of the Device ID field defined in section 7.6 of the IEEE std 1284-1994.

Field	Bit	Description
Unit_info ID	[031]	unit ID string

#### 4.2.2.6 IDV\_length

The IDV\_length field is used to inform the total length of the Vendor\_unique\_ID field for this Function\_unit leaf block. The value of this field will represent the field length in number of quadlets. (refer to above register map) If the

Vendor\_unique ID field is not used, the value of the IDV\_length will be 0.

Field	Bit	Description
IDV_length	[031]	length of Vendor_unique_ID field in
		quadlets

## 4.2.2.7 Vendor\_unique ID

The multi-quadlet Vendor\_unique ID field is used to inform an vendor specific information. The contents of this field will be dependent of the vendor.

Field	Bit	Description
Vendor_unique	[031]	vendor specific information
ID		

# 4.3 DDsr(1394.X) Command / Response Method

When using the DDsr(1394.X) Command / Response method, the information will be retrieved using Command/Response packets described in this chapter.

For this method, every DDsr(1394.X) protocol transaction will consist of

- one command
- one response

There are 2 command/response sets for the DDsr(1394.X) Protocol;

- INQUIRE\_DIRECTORY
- INQUIRE\_LEAF

Sending an INQUIRE\_DIRECTORY command to a DDsr(1394.X) compliant node will result in a response giving information on the supported function\_units within a node. In detail, it will give information on ;

- the function\_class of each unit in the node
- pointer to the Function\_unit leaf block for each unit

The INQUIRE\_LEAF command specifying a function unit will result in a response containing information of each of the function\_units within a node. In detail, it will give information on ;

- the protocols supported by the unit
- entry pointer of each of the protocols
- status information of the units

Information (ex. Plug and Play ID.) of a multi-function unit as a whole (multifunction information) can be retrieved using the INQUIRE LEAF command/respose as well..

The INQUIRE\_DIRECTORY command must be executed as an initial command to specify the response offset address.

Address offset locations noted in this section are with respect to a base address noted in the Node\_Dependent\_Info Directory offset in the configuration ROM.

# 4.3.1 INQUIRE\_DIRECTORY (unit discovery)

#### 4.3.1.1 COMMAND FORMAT

This command will inquire information on the availability of function units withn <u>a node</u>. The response packet will include a list of function\_units in the node. This command will also inform the printer the response offset address of the command source which the function should respond to.

0-7	8-15	16-23	24-31	
CR	CMD	INITno	deID	
response offset				

Field	Bit	Description	
CR	[07]	packet type	
		0 : COMMAND	
		others: reserved	
CMD	[815]	command type	
		0 : INQUIRE_DIRECTORY	
		others: reserved	
INITnodeID	[1631]	nodeID of node sending comand	
response offset	[031]	offset for response packets	

#### 4.3.1.2 RESPONSE FORMAT

The response will inform

• A list of Function\_units available in the node.

0-7	8-15	16-23	24-31			
CR	CMD	TARn	odeID			
	configuration state counter					
pointer						
fuctunit_class						
pointer						
fuctunit_class						

Field	Bit	Description	
CR	[07]	packet type	
		8 : RESPONSE/not implemented	
		9 : RESPONSE/accepted	
		10 : RESPONSE/rejected	
		11 : RESPONSE/in transition	
		others: reserved	
CMD	[815]	response(to command) type	
		0 : INQUIRE_DIRECTORY	
		others: reserved	
TARnodeID	[1631]	nodeID of target(node sending	
		response)	

The Configuration change counter field is a field which shows a value of a statechange ring counter. A state-change counter shall increment the value by 1 when there is a configuration change in the supported function units or the information of any of the functional units.

Field	Bit	Description
Configuration	[031]	counter value of state-change counter
state counter		

The Pointer field and Fuct.\_unit\_class field are the pair of fields that make up a unit block for each function\_unit in the Inquire\_directory response. The value of the Fuct.\_unit\_class field will represent the functional class of the unit, and the value of the pointer field will represent the pointer address of the Function\_unit leaf block of the unit it represents.

Field	Bit	Description
Pointer	[031]	pointer address of the Function_unit leaf block

Canon Inc.

TBD

Field	Bit	Description
Fuctunit_class	[031]	functional class of the unit
		0 : others
		1 : printing function
		2:
		:

## 4.3.2 INQUIRE\_LEAF (low-level service discovery)

#### 4.3.2.1 COMMAND FORMAT

This command will inquire the available datalink candidates for the requested function unit and the entry node and address for each of the datalinks.

0-7	8-15	16-23	24-31
CR	CMD	INIT n	ode ID
Pointer			

Field	Bit	Description
CR	[07]	packet type
		0 : COMMAND
		others: reserved
CMD	[815]	command type
		1 : INQUIRE_LEAF
		others: reserved
INITnodeID	[1631]	nodeID of image source device

The Pointer field will specify the address of the function unit information requested. The value of the pointer field can be obtained from the response of the INQUIRE\_DIRECTORY command

Field	Bit	Description
Pointer	[031]	pointer address of the Function_unit leaf block

#### 4.3.2.2 RESPONSE FORMAT

The response will inform

- the protocols supported by the requested unit
- entry pointer of each of the protocols
- status information of the requested units

Standard for Device and Service Discovery on an IEEE Std. 1394 Topology version 0.4

TBD

#### version 0.4

Field	Bit	Description
Status/Active	[30]	0 : unit is in non-active state
		1 : unit is in active state
Status/Error	[31]	0 : no error
		1 : error
	[1629]	reserved

The Status field is used to inform the basic (primitive) functional status of the unit.

The Protocol block is comprised of 3 fields; the Protocol\_name field, the entry\_node\_no. field, and the entry\_address field.

The Protocol block is comprised of 4 fields; the Protocol\_name field, the entry\_node\_no. field, and the entry\_address field with a key\_type to specify the characteristics of the entry\_address field.

The Protocol\_name field is a 3 quadlet field used to inform the supported datalinks of the function\_unit.

Field	Bit	Description
Protocol_name	[031]	The name of the datalink supported by
		the unit .

The entry\_node\_no. and entry\_address field will inform the node\_ID and the entry set address of the datalink noted above.

Field	Bit	Description	
entry_node_no.	[031]	nodeID	
key_type	[01]	1 : intial-register space offset for a immediate value	
		2 : indirect-space offset for a leaf	
		3 : indirect-space offset for a directory	
		others: not used.	
entry_address	[231]	address for datalink entry.	

The ID\_length field is used to inform the total length of the Unit\_info\_ID field for this Function\_unit leaf block. The value of this field will represent the field length in number of quadlets. (refer to above register map)

Field	Bit	Description
ID_length	[031]	length of Unit_info_ID field in quadlets

The multi-quadlet Unit\_info ID field is used to inform an unique ID of the function unit. The contents of the Unit\_info ID field will follow the format of the Device ID field defined in section 7.6 of the IEEE std 1284-1994.

Field	Bit	Description
Unit_info ID	[031]	unit ID string

The IDV\_length field is used to inform the total length of the Vendor\_unique\_ID field for this Function\_unit leaf block. The value of this field will represent the field length in number of quadlets. (refer to above register map) If the Vendor\_unique ID field is not used, the value of the IDV\_length will be 0.

Field	Bit	Description
IDV_length	[031]	length of Vendor_unique_ID field in quadlets

The multi-quadlet Vendor\_unique ID field is used to inform an vendor specific information. The contents of this field will be dependent of the vendor.

Field	Bit	Description
Vendor_unique	[031]	vendor specific information
ID		

# 4.4 Bus Reset - Reconnection

There are no DDsr(1394.X) protocol reconnection functions for re-establishing connection after a 1394 bus reset. In other words, the transport in progress when bus-reset occurs will be responsible for reconnection after bus reset is cleared. Naturally,

transport candidates for the DDsr(1394.X) protocol require support for reconnection functions in the case of a 1394 bus reset.

### **Bus Reset - Reconnection Requirements**

Values of the fields of the DDsr(1394.X) Protocol that will dynamically change;

- 1. shall not change during bus reset
- 2. shall be updated by the device upon reconnection with a time limit of 1sec after bus-reset is cleared. Methods of updating are beyond the scope of the proposal.

Devices connecting to DDsr(1394.X) compliant nodes shall keep track of the values of the Configuration-state counter field for any changes in configuration change of the node.

# 5. IEEE 1394 SPECIFIC ADDRESS SPACE

The IEEE1394 printer compliant with this specification should be compliant with IEEE1394 and IEEE1212 standards. This section will describe the CSR and Configuration ROM locations that the printer will implement. All locations are intended to comply with the IEEE1394 standard.

Address Locations noted in this section are with respect to a base address of:

FFFF F000 0000h

### 5.1 CSR

The printer will implement the following CSR's, as required by the IEEE 1394 standard. :

#### CORE CSRs

offset	0-7	8-15	16-23	24-31				
0000h		STATE_CLEAR						
0004h		STATE_SET						
0008h		NODE_IDS						
000Ch	RESET_START							
0010h								
0014h
